PHASE 3 – PROJECT DESIGN

Auto Ticket Classification Using Flow Designer

System Architecture

The system consists of the ServiceNow ticket table, Flow Designer, classification conditions, actions, assignment logic and notification components.

Input Design

The user enters ticket information such as short description and detailed description. These details are used by the flow for classification.

Processing Design

Flow Designer is triggered when a ticket is created or updated. It checks the ticket information against predefined conditions and identifies the appropriate classification.

Output Design

The system updates the ticket with the required category/classification and routes the ticket to the appropriate assignment group.

Flow Design

Trigger > Read Ticket Data > Check Conditions > Identify Classification > Update Ticket > Assign Ticket > Send Notification > End

Database/Table Design

The required ServiceNow ticket or incident table is used to store ticket information and classification details.

Security Design

Only authorized users can create, modify, test or administer the Flow Designer workflow and related ticket data.
